

Explanation of the CI Workflow Automation

This assignment demonstrates the implementation of a basic Continuous Integration (CI) workflow using GitHub Actions. The workflow was created inside the `.github/workflows` directory using a YAML configuration file named `ci.yml`. The workflow is configured to run automatically whenever code is pushed to the main branch or when a pull request is opened.

The workflow contains an automated job that runs on an Ubuntu virtual environment provided by GitHub Actions. The first step checks out the repository files using the `actions/checkout` action. The second step runs a simple command that prints “CI is running” to confirm that the workflow executes successfully.

This automation is useful because it allows developers to verify that workflows and commands run correctly whenever changes are made to the repository. Continuous Integration helps improve consistency, reduces manual work, and provides fast feedback during development. It is an important practice in modern software development because it helps teams maintain reliable and organized projects.
